column-span: all

A descendant with `column-span: all` cuts the current column group, occupies the container's full content width, and starts a fresh column group below. fulgur handles this inside the Taffy multicol hook by partitioning direct element children into alternating ColumnGroup / SpanAll segments and stacking them vertically.

Alpha paragraph sits in the left column of the first column group. The balance algorithm measures every child at the column width and packs them into the smallest per-column budget that still fits.

Beta paragraph follows alpha and may flow to the second column depending on the balance search. Both participate in the same ColumnGroup segment.

Gamma paragraph rounds out the first column group before the heading below interrupts it.

Full-width heading spans all columns

Delta paragraph begins a new column group below the heading. It is measured at the column width again, independent of the previous column group.

Epsilon paragraph continues the second column group. Balance runs separately for each ColumnGroup segment, so the heights above and below the span need not match.

Zeta paragraph completes the lower column group. The container height is the sum of all segment heights — two column groups plus the spanning heading.

This paragraph sits directly below the multicol container. The Taffy hook writes the post-layout size back into the document, so siblings after the multicol are positioned correctly without any reshape pass.
